Iteração 45
 $p_{\text{Adoecer}} = 0.5$, $p_{\text{Recuperar}} = 0.3$

Análise:

- No início da simulação, observa-se um rápido aumento no número de infectados, atingindo um pico antes de começar a decair.
- A quantidade de indivíduos recuperados aumenta progressivamente, enquanto o número de suscetíveis diminui de forma gradual.
- Em equilíbrio, a população de infectados tende a zero, restando apenas indivíduos suscetíveis e recuperados.
- A distribuição espacial da doença revela um padrão de clusters de infectados que se dissipam ao longo do tempo.

Iteração 45
 $p_{\text{Adoecer}} = 0.5$, $p_{\text{Recuperar}} = 0.9$

Análise:

- **pRecuperar = 0.1:** A recuperação é lenta, resultando em um longo período com alta população de infectados.
- **pRecuperar = 0.5:** A recuperação ocorre em ritmo moderado, equilibrando o tempo de propagação com a taxa de cura.
- **pRecuperar = 0.9:** A recuperação é muito rápida, limitando significativamente a propagação da doença.
- Quanto maior a probabilidade de recuperação, menor o pico de infectados e mais rápida é a estabilização do sistema.

Iteração 45
 $p_{\text{Adoecer}} = 0.5$, $p_{\text{Recuperar}} = 0.5$

Análise:

- **Cenário 1:** A doença se espalha rapidamente e persiste por mais tempo devido à baixa taxa de recuperação.
- **Cenário 2:** A doença é rapidamente contida, com poucos indivíduos infectados.
- **Cenário 3:** O sistema atinge um equilíbrio intermediário, com um pico moderado de infectados e uma proporção balanceada de recuperados.
- Cada cenário reflete dinâmicas distintas que ajudam a entender o impacto dos parâmetros no sistema.

Análise de Equilíbrio

In [158...

```
# Parâmetros
pAdoecer = 0.5
pRecuperar_values = np.linspace(0, 1, 11) # De 0 a 1 com 11 valores
populacao_final = {"Suscetíveis": [], "Recuperados": [], "Infectados": []}

for pRecuperar in pRecuperar_values:
    rec_final, susc_final, inf_final = [], [], []
    for seed in range(simulacoes):
        rec, susc, inf = simular_sir(L, pAdoecer, pRecuperar, max_iter, seed)
        rec_final.append(rec[-1])
        susc_final.append(susc[-1])
        inf_final.append(inf[-1])

    populacao_final["Suscetíveis"].append(np.mean(susc_final))
    populacao_final["Recuperados"].append(np.mean(rec_final))
```

```

populacao_final["Infectados"].append(np.mean(inf_final))

# Gráfico da análise de equilíbrio
plt.figure(figsize=(10, 6))
for classe, valores in populacao_final.items():
    plt.plot(pRecuperar_values, valores, label=classe)

plt.title("População Final vs Probabilidade de Recuperação")
plt.xlabel("Probabilidade de Recuperação (pRecuperar)")
plt.ylabel("População Média Final")
plt.legend()
plt.grid()
plt.show()

```

Análise:

- Em equilíbrio, a população de infectados tende a zero em quase todos os cenários analisados.
- A proporção final entre suscetíveis e recuperados depende fortemente de pRecuperar.
- **Baixo pRecuperar:** Maior número de indivíduos recuperados.
- **Alto pRecuperar:** Maior número de indivíduos suscetíveis permanecem intactos.

Análise Final da Atividade

Conclusões Principais:

- A dinâmica da propagação da doença é altamente sensível às probabilidades de contaminação e recuperação.
- Existe um equilíbrio dinâmico onde a doença é eventualmente erradicada, com o sistema alcançando um estado estável.

- Altos valores de recuperação limitam a propagação da doença, enquanto altos valores de contaminação aceleram seu espalhamento.
- Cenários extremos ajudam a ilustrar casos reais, como surtos descontrolados ou controle eficaz de epidemias.
